

# Track Collaboration Analysis

1. **Track collaborated with:** Data Science.
2. **Project dependency:** their no-show model consumes my outcome definition and engineered bands; my recommendations depend on knowing which drivers their model actually uses.
3. **Information/output received:** their completed Week 6 questionnaire — binary target decision (Cancelled dropped,  $F1 = 0.12$ ), feature list (no\_show\_rate, is\_weekend, is\_long\_distance, appointment\_load), baseline metrics (accuracy 46.0% vs 44.9% dummy; ROC-AUC 0.628 vs 0.499), and the waiting-time leakage note.
4. **Information/output provided:** HealthConnect\_Cleaned\_Data.csv with lead-time, distance and history bands; five KPI definitions with formulas; ranked driver list (lead time → history → distance).
5. **Integration activity completed:** definition-alignment exchange via the shared questionnaire plus file handover; I re-specified KPI 1 to exclude cancellations to match their binary target; they adopted my distance and history findings as model features.
6. **What changed as a result:** one agreed no-show definition across both tracks; my report now cites their recall-first metric as the technical counterpart of my cost framing; their feature set includes my bands; waiting time is formally excluded on both sides.
7. **Evidence:** (a) shared file HealthConnect\_Cleaned\_Data.csv in the repository; (b) their completed questionnaire PDF; (c) Section 9 of my Week 6 report; (d) GitHub commit adding the week-6 folder and shared file
